Extracellular matrix protein fibulin-1 plasma levels are associated with increased cardiovascular risk in chronic kidney disease

Alexandra Scholze, Peter Marckmann, Martin Tepel, Lars M. Rasmussen Department of Nephrology and Department of Clinical Biochemistry, Odense University Hospital, Odense, Denmark

Background

Fibulin-1 is one of the few extracellular matrix proteins present in blood in high concentrations. We aimed to define the relationship between plasma fibulin-1 levels and risk markers of cardiovascular disease in patients with chronic kidney disease..

Methods

Plasma fibulin-1 was determined in patients with chronic kidney disease (n=32; median age, 63 years; interquartile range, 51 to 73 years). Serological biomarkers related to cardiovascular disease (fibrinogen, interleukin 6, C-reactive protein) were measured. Arterial applanation tonometry was used to determine central hemodynamic and arterial stiffness indices.

Results

Tdisease he characteristics of chronic

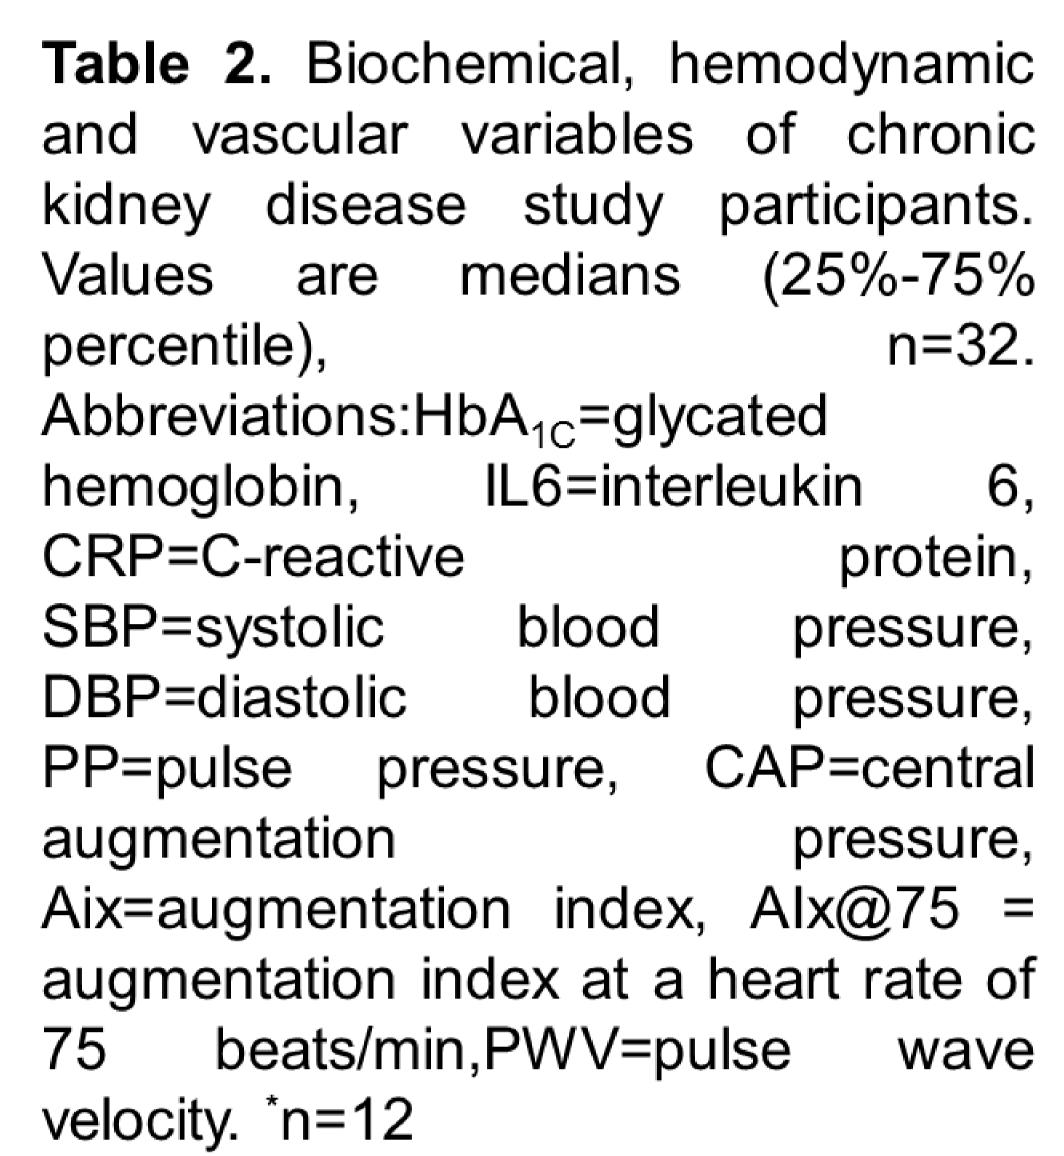

kidney study participants are shown Table 1. Biochemical, hemodynamic and vascular variables of chronic kidney disease study participants are given in Table 2 We observed a positive correlation of fibulin-1 levels with age (r=0.38; p=0.033), glycated hemoglobin (r=0.80; p=0.003), creatinine (r=0.35;p=0.045), and fibrinogen (r=0.39; p=0.027). Glomerular filtration rate fibulin-1 were inversely and correlated (r=-0.57; p=0.022). There was a positive correlation between fibulin-1 and central pulse pressure p=0.011) and (r=0.44; central pressure (r=0.55; augmentation multivariable p=0.001). In a diabetes, model, regression creatinine, fibrinogen and central augmentation pressure were independent predictors of plasma fibulin-1 (Table 3).

Table 1. Population characteristics of chronic kidney disease study participants. Values are medians (25 % - 75 % percentile) or numbers (percentages), n = 32. Abbreviations: ACE = angiotensin converting enzyme, AT = angiotensin, eGFR = estimated glomerular filtration rate, Kt/V = dialysis dose. * n = 16, eGFR determination only in patients without hemodialysis therapy. † n = 8.

Conclusions

Increased plasma fibulin-1 levels were associated with impaired kidney function and diabetes. Fibulin-1 levels were also associated with hemodynamic cardiovascular risk markers. We conclude, that fibulin-1 is involved in the pathogenesis of cardiovascular disease observed in chronic kidney disease
