

CKD Complications in Transplanted Patients Going Back to Dialysis : Which Impact on Prognosis

Julien Aniort, Saleh Kaysi, Aurélien Mulliez, Anne-Elisabeth Heng, Service de Néphrologie, Pôle REUNNIRH, Hôpital G. Montpied, CHU Clermont-Ferrand

Background

- Going back to dialysis after kidney transplantation is an important time in CKD patient life. It causes a sudden failure in quality of life and an increased risk of mortality and morbidity which induces repeated hospitalizations¹.
- CKD complications management in kidney transplanted patients returning to dialysis could be worse than that observed in patient starting dialysis for the first time^{2,3}.
- The adequacy of chronic kidney disease complications management could have an impact on kidney transplanted patients outcomes returning to dialysis.

Patients et Methods

- Retrospective observational multicentric study
- Comparing à group of T+ patients restarting dialysis to a group of T- patients starting dialysis due to native kidney failure
- Control group matched on age sex dialysis center, dialysis starting date and diabète mellitus.
- Data about CKD complications (arterial pressure, anemia, CKD-MBD, electrolyte disorder, dyslipidemia, nutrition status and inflammation) and outcomes (death and hospitalization) were collected retrospectively by consulting medical files
- KDOQI target value were used to determine management adequacy

Conclusion

A better attention to CKD complication notably Protein Energy Wasting should be taken in transplanted patient going back to dialysis
